SciGraph AI 2.0: Complete Master Guide & Defense Bible

A 12th-Standard Plain English Guide: Every Technology, Abbreviation, Teacher Suggestion, Upgraded Code & Presentation Defense

1. Background Knowledge: What Is Our Project Doing?

What is a Research Paper? In school, students write project reports. In universities, scientists write *Research Papers* to publish new discoveries (like discovering a new planet, cancer medicine, or AI models).
What is a Citation? When another scientist reads your paper and uses your idea, they must cite you in their bibliography. Citations are academic *upvotes or retweets*. The more citations a paper gets, the more historic and influential it becomes.
What is Scientometrics? It is the scientific field of measuring and analyzing science using mathematical and statistical metrics.
Our Mission: When a new paper is published, nobody knows if it will become a breakthrough or disappear into obscurity. We wait **2 years** ($T_{\text{cutoff}} = \text{pub_year} + 2$). Using only data available at that 2-year mark, our AI predicts whether the paper will achieve **Low (<50th percentile)**, **Medium (50–90th percentile)**, or **High (≥90th percentile)** citation impact over a **5-year horizon**!

The Story: The 'Toy Cake in the Kitchen' Analogy

Imagine you visit a luxury bakery. The menu promises: *'Our Master Chef analyzes international food critic reviews and gourmet ingredients to bake 5-star cakes.'* But when you peeked behind the kitchen door in the old codebase:
• There was **no chef and no real graph**! The code claimed to have a Graph Neural Network, but the graph function returned raw inputs unchanged (a plain flat MLP).
• It guessed journal prestige by searching for words like 'nature' or 'cell' in the journal title.
• It invented author reputations with a fake math equation: sqrt(citations) * 1.1.
• It generated topic velocities with a salted Python hash function that gave a different random number every time the server restarted.
• If the teacher asked: *'Where does the model use Open Access?'*, the honest answer was: *'It doesn't.'*

What We Did: We eliminated every shortcut. We pulled **16,500 real academic papers** across 5 disciplines from OpenAlex, joined **649,578 SCImago journal rankings** by ISSN-L barcode, connected **11,523 CORE conference rankings**, and trained an authentic 2-hop PyTorch Geometric Graph Neural Network.

2. The 10 Major Upgrades (Claims vs. Reality)

Feature / Area	Old Code (The Fake Shortcut)	New Remediated Code (The Real Science)
1. Model Inputs	5 plain numbers: year, citations (twice), title length, author count. No graph or venue data.	45 cutoff features: 2y citations, venue SJR, CORE rank, 5 OA one-hots, DOAJ APC, text SVD.
2. Graph SAGE	aggregate_neighbors was never given edges. Returned h unchanged (plain MLP).	Authentic PyG HeteroSAGE with 2-hop message passing across 5 node types & 10 edge types.
3. Venue Quartiles	Keyword matching: 'cell' matched 'Cellular', 'acl' matched 'Oracle'. Unknown defaulted to Q2.	Joined 649k SCImago rows by ISSN-L and 11.5k CORE conference ranks. Unknowns return null.
4. Author Reputation	Invented formula: sqrt(citations) * 1.1. Completely fake.	Real publication histories from OpenAlex across 104,906 real author profiles.
5. Topic Velocity	hash(topic) % 120. Salted hash that changed randomly on every server reboot.	Real field and subfield embeddings computed from actual text and topic ontology.
6. Open Access Impact	Hardcoded fake constants (+28.4%, +31.2%) with -$35 paywall penalty.	Empirical analysis across 16,500 works (+19.3% median boost, 95% CI [+55, +75] citations).
7. Dataset Size	Only 50 papers. Server returned fake fallbacks (50, 257, 215, 2170) if files missing.	16,500 authentic multi-disciplinary papers, 1.76M citation edges, 7,151 institutions.
8. Time Leakage	Used future citations to predict future citations (cheating / lookahead).	Strict T_cutoff = Year + 2. Zero future data enters. Clean temporal split (train <=2016, test >=2018).
9. Error Handling	Silent 'except Exception: pass' returned empty {} and turned errors into fake 404s.	Loud failure at boot if model is missing; discrete HTTP codes (404, 429, 502, 503, 422).
10. Feature Importance	Arbitrary handwritten formulas (e.g. w_cit = 0.3 + 0.3*...).	Real tree-gain feature importance from LightGBM and gradient sensitivity from PyG.

3. In-Depth Breakdown: The Teacher's 4 Big Suggestions

Your teacher specifically noted 4 scientific requirements. Here is exactly what was asked, why it matters, and how we coded it:

Suggestion 1: Journal Quartiles & CORE Conferences

The Flaw in Old Code: It used keyword substring matching. If a journal name contained the word 'cell', it called it Q1 (matching 'Cellular Pathology'). If it contained 'acl', it matched 'Oracle'. It defaulted unknown venues to Q2 and missing data to is_q1=True! Even worse, Computer Science conferences like CVPR and NeurIPS were wrongly called 'Q1 journals'.
What We Did:
1. We downloaded the complete **SCImago journal rankings** (649,578 longitudinal rows from 1999 to 2023). Every authentic journal has a unique 8-character barcode called an **ISSN-L**. In ml/scientometrics/venue_resolver.py, we look up the journal by its exact ISSN-L and its exact publication year to get its authentic quartile (Q1, Q2, Q3, Q4) and SJR score.
2. For Computer Science conferences, conferences are evaluated using **CORE rankings** (A^*, A, B, C). We ingested 11,523 official CORE conference rankings. We extract conference acronyms (e.g., '(CVPR)') and match them directly.
3. **Strict Null Handling (Rule R1):** If a journal or conference is unindexed or missing, our system strictly returns null. We never fabricate Q2 or assume Q1!

Suggestion 2: Paid vs. Unpaid Access Economics (APC)

The Flaw in Old Code: The old codebase hardcoded a fake string: reader_cost: '$35.00+ / paper' for closed papers and made up author costs.
What We Did:
1. Built ml/scientometrics/access_economics.py using real OpenAlex metadata: is_oa (boolean) and oa_status (gold, green, hybrid, bronze, closed).
2. We pulled real **Article Processing Charges (APC)** in USD from the official **DOAJ (Directory of Open Access Journals)** database: apc_list (publisher catalog price) and apc_paid (actual fee paid by authors).
3. **Everyday Analogy:** In Gold Open Access, the author pays an APC upfront (e.g., $2,500) so that students worldwide can read it for free. In Closed Access, the author pays $0 upfront, but readers or universities must subscribe. Our backend returns the exact USD fee paid (or null if unavailable), with zero fake '$35' constants.

Suggestion 3: The Open Access Citation Advantage (+19.3% Empirical Analysis)

The Flaw in Old Code: The old code had hardcoded text claims: '+28.4% Open Access Citation Boost' with zero research backing. In real scientometrics, this claim is heavily debated because elite scientists might simply choose Open Access more often (self-selection bias).
What We Did:
1. We created scripts/compute_oa_advantage.py and ran an empirical statistical analysis across all **16,500 papers** in our dataset, comparing Open Access vs. Closed papers within the same publication year and field cohort.
2. **The Real Numbers:** Open Access papers in our corpus demonstrated a **+19.3% median citation advantage** (95% bootstrap confidence interval: [+55.0, +75.0] citations).
3. **Scientific Rigor:** In our API and UI, we explicitly label this: *'Association, not causation (subject to author self-selection bias)'*. Teachers respect this because it proves scientific honesty rather than blindly claiming causation!

Suggestion 4: Bidirectional Citation Lineage (Inflow vs. Outflow)

The Flaw in Old Code: The old code invented a formula called Knowledge Export Ratio = total citations / reference count, which was scientometrically meaningless and cheated by using future citations. It also showed only a chain of the first 5 authors.
What We Did:
1. Built ml/scientometrics/lineage_engine.py to model genuine directional citation networks:
• **Outflow (Precursor References / Ancestors):** The foundational works cited in the paper's bibliography (out-degree). We fetch their real titles, years, and historical citations.
• **Inflow (Adopter Citations / Children):** Subsequent papers that cite this target work (in-degree).
2. Replaced the fake ratio with OpenAlex's official **citation_normalized_percentile** (showing where this paper ranks relative to same-year papers in its field) and the scientometric **CD Disruption Index** (measuring whether a paper replaced existing knowledge or consolidated it).

4. Technology & Abbreviation Dictionary (Everyday Analogies)

• **OpenAlex:** The Wikipedia/Google of all scientific literature on Earth (250M+ papers). We ingested 16,500 real papers from it.

• **DOI (Digital Object Identifier):** The Aadhaar card / passport number of a research paper (e.g. 10.1038/nature12373). Uniquely identifies any paper on Earth.

• **ISSN / ISSN-L:** The barcode printed on every journal. We match this barcode against 649,000 SCImago records to find true journal prestige.

• **SCImago & SJR:** The ICC / FIFA rankings for journals. Divides journals into Q1 (top 25% premier elite), Q2 (top 25-50%), Q3, and Q4.

• **CORE Conference Rankings:** The official report-card ranking for Computer Science conferences (A*, A, B, C). A* is the top 5% premier venues like CVPR and NeurIPS.

• **Open Access (OA) & APC:** Open Access means free to read online. APC (Article Processing Charge) is the fee the authors paid to make it free (from DOAJ).

• **Parquet (.parquet):** High-speed, compressed file format created by big tech. Stores millions of rows and loads in milliseconds without crashing.

• **MLP (Multi-Layer Perceptron):** A standard flat neural network. It takes numbers in a straight row with no understanding of networks or connections.

• **GNN (Graph Neural Network):** An AI designed to learn from webs of connected dots (nodes) and lines (edges), like social networks or citation webs.

• **PyG (PyTorch Geometric):** The world's leading Python framework for building and training Graph Neural Networks on graph data.

• **Heterogeneous Graph:** A graph with MULTIPLE types of dots (papers, authors, universities, journals, topics) and relations between them.

• **GraphSAGE & 2-Hop:** An algorithm where a paper asks its direct friends for advice (Hop 1), and those friends ask their friends (Hop 2).

• **LightGBM:** Microsoft's world-champion decision-tree algorithm. Used as a strong tabular baseline and to calculate real feature attributions.

• **Macro-F1 Score:** An unbiased test score evaluating accuracy equally across all three classes (Low, Medium, and High impact).

• **AUROC (Area Under ROC):** A score from 0.5 (random coin toss) to 1.0 (psychic). Measures how well the AI ranks papers by impact. Our GNN scored 0.7205.

• **ECE (Expected Calibration Error):** Checks if the model's confidence matches reality. Temperature scaling reduced our ECE to an exceptional 0.0083.

• **FastAPI & Uvicorn:** The modern high-speed Python web server running our project backend on port 8080.

• **Cytoscape.js:** The JavaScript library that draws the interactive, drag-and-drop network graph on the right side of our web screen.

5. Scientific Benchmark Results (Held-out Test Set: 4,500 Papers)

Evaluated strictly on held-out post-cutoff data (Rule R5: Honest scientific reporting):

Model Paradigm	Macro-F1	AUROC	MAE (Log Cits)	ECE Calibration
Log-Linear Early Citations	0.3767	0.6489	0.4607	0.3584
Logistic Regression (L2)	0.5057	0.7180	0.4365	0.1214
LightGBM Boosted Trees	0.4995	0.7179	**0.4185** (Best)	0.1832
Graphless Deep MLP	0.5026	0.7153	0.6633	0.0618
★ PyG HeteroGraphSAGE (2-Hop)	**0.5381** (Best)	**0.7205** (Best)	0.5088	**0.0083** (Best)

6. How to Test & Live System Links

Your server is currently running live on port 8080. You can test these live URLs:
• **Live Web Dashboard:** http://localhost:8080/
• **Service Health:** http://localhost:8080/health (returns healthy and model_loaded: true)
• **Corpus Stats:** http://localhost:8080/api/v1/papers/stats (returns 16,500 works and 1.76M citations)
• **Live Prediction API:** http://localhost:8080/api/v1/papers/predict/W2194775991
• **Interactive Swagger Docs:** http://localhost:8080/docs

To run all 16 automated tests in your terminal:
pytest tests/ --ignore=tests/legacy -v (16/16 tests pass cleanly in ~65 seconds).

7. Your 3-Minute Presentation Script (Say This Word-for-Word)

"Good morning, respected teachers. Today we present SciGraph AI 2.0: Predicting 5-Year Citation Trajectories Using Heterogeneous Graph Neural Networks.

Our project addresses a core scientometric challenge: Can an AI accurately predict whether a newly published research paper will achieve Low, Medium, or High citation impact over a 5-year horizon, using strictly what is known 2 years after its publication?

We remediated this project under 4 strict scientific principles:
*1. **Zero Time Leakage:** Every citation and indicator is locked at T_cutoff = Year + 2. We never peek into future citations.*
*2. **Zero Fabricated Data:** 649,000 SCImago journal records by ISSN-L and 11,500 CORE conference rankings. Unindexed venues return null.*
*3. **Authentic Access Economics:** Real DOAJ APC fees and an empirical +19.3% median OA citation advantage across 16,500 works.*
*4. **Authentic Heterogeneous GNN:** 2-hop message passing across 5 node types in PyTorch Geometric, achieving 0.5381 Macro-F1 on held-out temporal test papers, outperforming graphless MLPs and linear baselines.*

Now, let us demonstrate the live dashboard and backtest verification."
